

2.1Pr

The form used for describing preparations is: substrate reagent

a **HHal** / 20° (room temp) or Δ if necessary

concentrated aqueous acids

		HCl	HBr	HI
ROH	te	yes	yes	yes
	se	no	yes (slow)	yes
	pm	no	no	yes

but not with Cl^- or Br^- (weaker Nu^- , 1.11Ge)

Potency of HHal increased by using e.g.

'dry' HBr (no H_2O) reaction potentially reversible, absence of H_2O drives reaction

'dry' HBr / sq H_2SO_4 increases amount of protonated alcohol (sq = small quantity)

b **P-Hal reagents**

driving force is formation of very strong PO double bond

yields pm > se > te \leftarrow tend to give elimination

PHal₃ (Cl, Br, I) or mixtures P / Br₂, P / I₂

PBr_3 / / 10° is good method

several modern developments e.g. PPh_3 / Br₂, PPh_3 / CCl_4

c **SOCl₂ (thionyl chloride)**

simple representation:

yields as in b

3 **RHal** (i.e. from halides obtained by the other methods given here)

direction contrary to expectation from nucleophilicities in aprotic solvents (Section 1.13);
reaction driven by precipitation of NaCl (or Br)

1 With Nu⁻ Yields pm—good, se—modest, te—poor

see notes about i, j and k at bottom of this scheme

AgCN reaction is complex, reliable results not available for many R-Hal; not general Pr of R-NC

Friedel-Crafts reaction, mechanism different from others here, range of R-Hal can be used

2.1Re

Δ unless stated otherwise
